

Agent Income Estimation Tool — Consolidated Requirements and User Stories

Author: Manus AI

Source Basis: User-provided screenshots of the “Income Estimation Tool: Methodology & Data Documentation,” Version 1.0, Draft for Legal/OGC Review, as of May 27, 2026.

Document Purpose: This document consolidates the business requirement document into logical user stories that can be used by product, business analysis, engineering, QA, and Legal/OGC review teams.

1. Executive Consolidation

The Agent Income Estimation Tool is intended to support recruiting conversations by helping prospective agents and financial professionals estimate potential **first-year commission income** using a small set of candidate-facing inputs. The source methodology explicitly positions the output as a **hypothetical estimate**, not a guarantee of income. The estimate is based on historical internal agent performance data, candidate activity assumptions, and the candidate’s selected client market segment.[1]

The logical flow can be separated into five user stories. The first story covers **candidate input capture**. The second covers **market segment mapping**. The third covers **income estimate calculation**. The fourth covers **results presentation and candidate-facing sensitivity scenarios**. The fifth covers **data governance, traceability, assumptions, and Legal/OGC controls**. This structure keeps the requirements aligned to the way a user experiences the tool while preserving the data and compliance logic needed behind the scenes.

Story ID	User Story Name	Logical Flow Area	Primary Actor	Business Outcome
US-01	Capture Candidate and Activity Inputs	Candidate intake	Recruiter / Candidate	Collect the minimum required information needed to estimate first-year income.

US-02	Map Market Served to Income Segment	Market mapping	Candidate / System	Select the correct historical income range based on intended client market.
US-03	Calculate Base First-Year Income Estimate	Calculation engine	System	Convert market and activity inputs into a point estimate and bounded range.
US-04	Present Results and Sensitivity Scenarios	Results experience	Candidate / Recruiter	Display estimate and optional what-if scenarios in a candidate-facing manner.
US-05	Maintain Data Foundation, Assumptions, and Compliance Traceability	Governance	Product Owner / OGC / Administrator	Ensure calculations are auditable, bounded, and aligned with approved methodology.

Key interpretation: The business flow does not require many unrelated stories. It is best represented as **five logically segregated user stories** because the BRD describes one primary candidate journey supported by calculation, presentation, and governance layers.

2. Consolidated Requirement Inventory

The source BRD describes a tool that uses the candidate's **Market Served**, **Working Weeks per Year**, and **Appointments Kept per Week** to determine an estimated first-year FYC range. Additional candidate or system fields, such as Candidate Name, Candidate State, Registered Rep, and TAS Plan, support identification, eligibility, or downstream plan logic, but the visible methodology primarily uses market and activity inputs to produce the base estimate.[1]

Requirement Category	Consolidated Requirement	Key Rules Captured from BRD
----------------------	--------------------------	-----------------------------

Candidate identification	Capture candidate name and candidate state.	Candidate Name is a free-text identifier. Candidate State is self-selected from applicable states.
Candidate business profile	Capture Market Served, Registered Rep status, and TAS Plan where applicable.	Market Served options are Mass Market, Mid Market, Affluent, and High Net Worth. Registered Rep defaults to Yes. TAS Plan is automated based on state availability where applicable.
Activity assumptions	Capture Working Weeks per Year and Appointments Kept per Week.	Working weeks suggested range is 45–50. Appointments suggested range is 1–9 with a floor of 1 and ceiling of 9.
Segment mapping	Map selected market to historical FYC range.	Market segment ranges are derived from 2024 FYC deciles after filtering out top and bottom 1% outliers.
Base calculation	Calculate activity position, point estimate, and displayed range.	Appointment position is interpolated from anchor points; working weeks are applied as a scalar; range is $\pm 10\%$ of segment spread and bounded by segment limits.
Results screen	Display base estimate and optional sensitivity levers.	Sensitivity levers are “Make One More Sale Weekly” and “30% Conversion Increase” ; both are post-calculation adjustments, not primary inputs.
Data governance	Ensure traceability and compliance review.	Outputs must be traceable to historical 2024 data and should not exceed observed bounds. OGC review remains open for key candidate-facing constructs.

3. User Stories

US-01 — Capture Candidate and Activity Inputs

User Story

As a **recruiter or prospective candidate**, I want to enter a small number of candidate profile and activity inputs so that the tool can generate a first-year income estimate using a simple, guided candidate-facing flow.

Description

This story covers the initial intake experience. The tool must collect the fields needed to identify the candidate, understand the candidate's intended market, determine applicable plan or state-specific logic, and capture the candidate's expected first-year activity. The intake flow should be concise because the tool is designed for recruiting conversations and should not require extensive data entry.

The BRD identifies the following inputs: Candidate Name, Working Weeks per Year, Market Served, Registered Rep, TAS Plan, Appointments Kept per Week, and Candidate State. The primary estimation-driving inputs are Market Served, Working Weeks per Year, and Appointments Kept per Week. Other fields support identification, business context, defaults, state-based availability, or downstream calculations.[1]

Field-Level Requirements

Field	Input Type	Source / Provisioning	Options or Range	Validation Expectation
Candidate Name	Free text	Automated or entered identifier	Not applicable	Must support a candidate identifier; no numeric calculation depends on this field.
Working Weeks per Year	Numeric	Self-entered	Suggested 45–50	Must accept values within the approved logical range and prevent non-numeric entries.

Market Served	Single-select	Self-selected	Mass Market, Mid Market, Affluent, High Net Worth	Must be required because it determines the income segment.
Registered Rep	Yes / No	Self-selected	Defaults to Yes	Must allow Yes or No and preserve default behavior.
TAS Plan	System-derived	Automated	Builder XP / Maximizer, where applicable	Must be determined based on candidate state availability where relevant.
Appointments Kept per Week	Numeric	Self-entered	Suggested 1–9	Must enforce floor of 1 and ceiling of 9.
Candidate State	Single-select	Self-selected	All applicable states	Must support applicable state list and drive plan availability where needed.

Example

A recruiter is speaking with a candidate named Jane Smith. Jane expects to work 47 productive weeks in her first year, plans to serve the Mid Market, expects to keep 4 appointments per week, is operating in an applicable state, and keeps the default Registered Rep value of Yes. Once these inputs are entered, the system has enough information to select the Mid Market segment and calculate a candidate-facing estimate.

Acceptance Criteria

AC ID	Given	When	Then
US01-AC01	The recruiter opens the income estimation intake flow	The page loads	The system displays all required candidate and activity input fields in a clear sequence.

US01-AC02	A candidate name is available	The name field is populated	The system stores the name as an identifier and does not use it in the income calculation.
US01-AC03	The user enters Working Weeks per Year	The value is outside the accepted numeric range	The system prevents calculation and displays a validation message explaining the accepted range.
US01-AC04	The user enters Appointments Kept per Week	The value is below 1 or above 9	The system prevents calculation and explains that the logical floor is 1 and ceiling is 9.
US01-AC05	The user selects Candidate State	The state has TAS plan implications	The system automatically determines the applicable TAS plan option where applicable.
US01-AC06	The user does not change Registered Rep	The form is submitted	The system uses the default value of Yes unless the user explicitly selects No.
US01-AC07	Any required calculation-driving field is missing	The user attempts to calculate	The system identifies the missing field and does not produce an estimate until it is completed.

Notes and Dependencies

The visible BRD states that the Working Weeks range of 45–50 and the Appointments range of 1–9 were treated as logically appropriate. The implementation should confirm whether values outside the suggested ranges are strictly blocked or merely warned, but the screenshots indicate that the appointment floor and ceiling should be enforced.

US-02 — Map Market Served to Income Segment

User Story

As a **prospective candidate**, I want my selected client market to map to an appropriate historical income range so that the estimate reflects the type of market I intend to serve.

Description

This story covers the business logic that translates the candidate’s Market Served selection into an income range. The BRD defines four market segments: Mass Market, Mid Market, Affluent, and High Net Worth. These segments are mapped to historical FYC ranges using the 2024 first-year prior agent income distribution after filtering out the top and bottom 1% of agents by FYC.[1]

The 2024 FYC distribution is divided into ten deciles. Each market segment spans multiple deciles, and adjacent segments intentionally overlap. This overlap reflects the practical reality that candidates serving adjacent markets may have similar outcomes at the edges of the distribution.

Segment Mapping Requirements

Market Served	Decile Mapping	FYC Range	Business Interpretation
Mass Market	D1–D5	\$1,839–\$22,471	Lower half of the retained distribution.
Mid Market	D3–D7	\$9,589–\$30,872	Centered on the population median.
Affluent	D5–D9	\$17,839–\$53,504	Upper-middle range of the retained distribution.
High Net Worth	D8–D10	\$30,917–\$116,268	Top three deciles, anchored above the population median.

The High Net Worth segment requires special handling. The BRD indicates that High Net Worth is anchored at Decile 8 rather than a strict fourth quartile because agents serving high-net-worth markets write larger cases by nature. The range ceiling is the actual 99th percentile of the 2024 data, shown as approximately \$116,268.[1]

Example

If a candidate selects **Affluent** as the Market Served, the system must use the Affluent segment range of approximately **\$17,839 to \$53,504**. The candidate's activity position will then determine where within that Affluent range the estimate lands.

Acceptance Criteria

AC ID	Given	When	Then
US02-AC01	The user selects Mass Market	The estimate is calculated	The system uses the D1–D5 range of \$1,839–\$22,471 as the segment boundaries.
US02-AC02	The user selects Mid Market	The estimate is calculated	The system uses the D3–D7 range of \$9,589–\$30,872 as the segment boundaries.
US02-AC03	The user selects Affluent	The estimate is calculated	The system uses the D5–D9 range of \$17,839–\$53,504 as the segment boundaries.
US02-AC04	The user selects High Net Worth	The estimate is calculated	The system uses the D8–D10 range of \$30,917–\$116,268 as the segment boundaries.
US02-AC05	Adjacent market segments overlap	The user compares segment ranges	The system preserves the approved overlapping segment ranges and does not force mutually exclusive non-overlapping ranges.
US02-AC06	The market mapping table is pending Legal/OGC confirmation	The tool is prepared for candidate-facing use	The implementation must flag this mapping as requiring approval before final production release.

Notes and Dependencies

The market mapping logic is one of the explicit open Legal/OGC review items. Product and compliance stakeholders should confirm the candidate-facing labels and whether the ranges should be displayed exactly, rounded, or formatted as broader bands.

US-03 — Calculate Base First-Year Income Estimate

User Story

As the **system**, I want to calculate a first-year income estimate from the selected market segment and activity inputs so that the candidate receives a bounded, historically traceable income range.

Description

This story covers the core calculation engine. The calculation has two major steps. First, the selected Market Served determines the candidate's segment minimum and segment maximum. Second, the candidate's activity inputs determine the candidate's position within that segment range.

The activity calculation uses **Appointments Kept per Week** and **Working Weeks per Year**. Appointment position is calculated by linear interpolation between benchmark anchor points. Working weeks are then applied as a proportional scalar, calculated as Working Weeks divided by 50. The final activity position is Appointment Position multiplied by the Working Weeks scalar.[1]

Calculation Rules

Calculation Component	Rule
Appointment floor	1 appointment per week maps to activity position 0.00.
Population average anchor	2.6 appointments per week maps to activity position 0.40.
Top 25% anchor	6.46 appointments per week maps to activity position 0.70.
Appointment ceiling	9 appointments per week maps to activity position 1.00.
Appointment interpolation	Any value between anchors is calculated proportionally between the two surrounding anchor points.

Working weeks scalar	$\text{Working Weeks} \div 50.$
Final activity position	$\text{Appointment Position} \times \text{Working Weeks Scalar}.$
Point estimate	$\text{Segment Minimum} + (\text{Activity Position} \times \text{Segment Spread}).$
Displayed range low	$\max(\text{Segment Minimum}, \text{Point Estimate} - 0.1 \times \text{Segment Spread}).$
Displayed range high	$\min(\text{Segment Maximum}, \text{Point Estimate} + 0.1 \times \text{Segment Spread}).$

Example

A candidate selects **Mid Market**, enters **47 working weeks**, and expects **4 appointments per week**. The system identifies the Mid Market segment range, calculates the appointment position by interpolating between the 2.6 and 6.46 appointment benchmarks, applies the 47/50 working week scalar, and produces a displayed range. The BRD's illustrated example for this scenario shows annual appointments of **188**, activity position of **0.62**, and estimated range of approximately **\$21,100–\$24,500**.^[1]

Acceptance Criteria

AC ID	Given	When	Then
US03-AC01	A valid Market Served selection exists	The calculation starts	The system retrieves the correct segment minimum, maximum, and spread.
US03-AC02	Appointments Kept per Week equals 1	Appointment position is calculated	The system returns appointment position 0.00.
US03-AC03	Appointments Kept per Week equals 2.6	Appointment position is calculated	The system returns appointment position 0.40 before applying the weeks scalar.
US03-AC04	Appointments Kept per Week equals 6.46	Appointment position is calculated	The system returns appointment position 0.70 before applying the weeks scalar.

US03-AC05	Appointments Kept per Week equals 9	Appointment position is calculated	The system returns appointment position 1.00 before applying the weeks scalar.
US03-AC06	Appointments Kept per Week falls between two benchmark anchors	Appointment position is calculated	The system uses linear interpolation between the two surrounding benchmark positions.
US03-AC07	Working Weeks per Year is provided	Activity position is calculated	The system multiplies appointment position by Working Weeks divided by 50.
US03-AC08	Activity position and segment range are available	Point estimate is calculated	The system applies Segment Minimum + (Activity Position × Segment Spread).
US03-AC09	The displayed range is calculated	The lower or upper bound exceeds segment boundaries	The system floors the low value at the segment minimum and caps the high value at the segment maximum.
US03-AC10	The calculation produces an output	The result is displayed	The result must be a range, not only a single number.
US03-AC11	Any calculation input is invalid or missing	The calculation is requested	The system does not calculate and returns a clear validation message.

Notes and Dependencies

The screenshots provide the calculation formula and benchmark anchors, but engineering should confirm numeric rounding rules for activity position, annual appointments, point estimate, and displayed currency values. The BRD examples appear rounded for candidate-facing display.

US-04 — Present Results and Sensitivity Scenarios

User Story

As a **prospective candidate or recruiter**, I want to see the estimated income range and optional scenario adjustments so that I can understand how activity changes may influence the estimate without confusing those scenarios with guaranteed outcomes.

Description

This story covers the results screen. The BRD states that the output should be shown as a range, not a single number. It also describes two optional candidate-facing adjustments on the results screen: **Make One More Sale Weekly** and **30% Conversion Increase**. These are not separate primary inputs; they are sensitivity levers shown after the base estimate has been calculated.[1]

The results screen should clearly distinguish the base estimate from sensitivity scenarios. Because the source document is pending OGC review, the language, placement, and labeling of these scenario constructs must be controlled carefully before candidate-facing release.

Results and Scenario Requirements

Result Element	Requirement	Candidate-Facing Interpretation
Base estimated range	Display the calculated low and high estimate.	Candidate sees a bounded estimate derived from their selected market and activity assumptions.
Annual appointments	Display or make available annual appointments when appropriate.	Candidate can understand how weekly appointments translate into annual activity.
Activity position	Display internally or optionally on screen depending on design.	Recruiter or system can explain how activity influences placement within the range.
Make One More Sale Weekly	Recalculate assuming one additional appointment per week above stated input.	Candidate sees the potential estimate effect of increased weekly activity.
30% Conversion Increase	Model a 30% improvement in activity-to-income position within the segment range.	Candidate sees a scenario reflecting improved conversion or productivity.
Disclaimer language	Display that results are estimates and not income	Candidate understands that actual results depend on

guarantees.

individual performance and external factors.

Example

A candidate receives a base estimate of **\$21,100–\$24,500** for a Mid Market scenario. The recruiter can toggle **Make One More Sale Weekly** to show how the estimate changes if the candidate keeps one additional appointment per week. The recruiter can also toggle **30% Conversion Increase** to model improved activity-to-income positioning. The screen should make clear that these are **sensitivity scenarios**, not promises or guaranteed compensation outcomes.

Acceptance Criteria

AC ID	Given	When	Then
US04-AC01	A base estimate has been calculated	The results screen loads	The system displays the estimated income range clearly and prominently.
US04-AC02	The base estimate is displayed	The candidate views the result	The system presents the result as a range and not as a guaranteed single income figure.
US04-AC03	The user toggles Make One More Sale Weekly	The scenario is applied	The system recalculates using one additional appointment per week above the candidate's stated appointment input, subject to applicable caps.
US04-AC04	The user toggles 30% Conversion Increase	The scenario is applied	The system models a 30% improvement in activity-to-income position within the selected segment range.

US04-AC05	A sensitivity scenario is active	The result is shown	The system clearly labels the output as a scenario or sensitivity view and distinguishes it from the base estimate.
US04-AC06	The candidate views any result	The result is displayed	The system includes disclaimer language indicating that outputs are hypothetical estimates and not guarantees of income.
US04-AC07	Legal/OGC has not approved scenario wording	The release is being prepared	The system must not publish final candidate-facing language for these constructs without required approval.

Notes and Dependencies

The **Make One More Sale Weekly** construct and **30% Conversion Increase** construct are both open OGC items. The implementation should support the calculation capability, but the final screen labels, explanatory copy, and placement should remain configurable until approved.

US-05 — Maintain Data Foundation, Assumptions, and Compliance Traceability

User Story

As a **product owner, Legal/OGC reviewer, or system administrator**, I want the tool's assumptions, data sources, and calculation outputs to be traceable and controlled so that the candidate-facing estimate remains auditable, compliant, and aligned with approved methodology.

Description

This story covers the governance layer behind the candidate experience. The BRD relies on internal 2024 agent performance records, with the population limited to First-Year Prior

agents active through their 12th month. PEA agents are excluded, and the top and bottom 1% of agents by FYC are removed before analysis. The retained sample size is shown as **N = 1,873**, representing the middle 98% of the 2024 1P agent class. A parallel 2023 dataset was used as a reference check on key distributions.[1]

The governance layer should preserve the source tables, calculation parameters, validation status, and open Legal/OGC items. It should also ensure the tool cannot generate values outside the historical bounds defined by the approved population and segment ranges.

Data and Governance Requirements

Governance Area	Requirement	Implementation Expectation
Source population	Use 2024 internal 1P agent records active through month 12.	Data version should be documented and reproducible.
Exclusions	Exclude PEA agents and remove top/bottom 1% FYC outliers.	Filtering logic should be documented and testable.
Final sample size	Preserve the post-filter sample size of N = 1,873 for the 2024 methodology.	Any future refresh must record new sample sizes and approval status.
Verification dataset	Maintain reference to 2023 dataset check.	Comparison should be retained for auditability where available.
Segment ranges	Store approved decile and segment tables.	Calculations should read from controlled configuration rather than hard-coded unreviewed values.
Activity benchmarks	Store appointment anchor points and working weeks scalar rule.	Changes should require versioning and review.
Output band	Store $\pm 10\%$ of segment spread banding rule.	OGC must confirm whether this band remains appropriate.
Growth and persistency assumptions	Preserve annual growth and 98% persistency assumptions if used in broader modeling.	These assumptions should not affect first-year base estimate unless explicitly implemented.
Open OGC items	Track unresolved items before production release.	Release readiness should depend on required approvals.

Example

A product owner updates the market segment table after Legal/OGC approval. The system stores the new version, effective date, approver, and rationale. All future estimates use the approved configuration, while prior estimates remain traceable to the version that produced them.

Acceptance Criteria

AC ID	Given	When	Then
US05-AC01	The calculation configuration is reviewed	A stakeholder inspects the tool methodology	The system or supporting documentation identifies the source data year, population definition, exclusions, and final sample size.
US05-AC02	A calculation result is generated	An audit review is performed	The result can be traced to the market segment range, activity benchmarks, and calculation formula used at the time of generation.
US05-AC03	A calculated value would exceed a segment boundary	The displayed range is produced	The system floors or caps the displayed range at the approved segment boundaries.
US05-AC04	A future data refresh is introduced	Configuration is updated	The system stores the new data version and does not overwrite historical methodology without version control.
US05-AC05	OGC review items remain unresolved	Production release is assessed	The system or release checklist identifies unresolved approvals for sensitivity constructs, market served table, and output band.

US05-AC06	Growth rate or persistency assumptions are displayed or used	A stakeholder reviews calculations	The system distinguishes assumptions used for first-year estimate calculation from assumptions used only for broader modeling or context.
US05-AC07	The tool is used in a recruiting conversation	Candidate-facing output is shown	The result includes appropriate disclaimer language stating that outputs are hypothetical estimates and not guarantees.

Notes and Dependencies

The source BRD includes an annual growth rate section and a 98% persistency assumption. Based on the visible screenshots, those assumptions appear relevant to broader modeling or future-year projections, while the primary first-year estimate is driven by market segment and activity inputs. If the product scope includes multi-year projections, an additional user story should be added for future-year income modeling.

4. Cross-Story Business Rules

The following business rules apply across multiple stories and should be treated as shared implementation rules rather than isolated screen requirements.

Rule ID	Business Rule	Applies To
BR-01	Outputs must be hypothetical estimates and must not be presented as guaranteed income.	US-04, US-05
BR-02	The tool must produce a range, not only a single number.	US-03, US-04
BR-03	Market Served determines the segment minimum and maximum FYC range.	US-02, US-03

BR-04	Appointments Kept per Week must be mapped to activity position using approved benchmark anchors and interpolation.	US-03
BR-05	Working Weeks per Year must be applied as Working Weeks divided by 50.	US-03
BR-06	Displayed range must use $\pm 10\%$ of segment spread around point estimate, bounded by segment minimum and maximum.	US-03, US-04
BR-07	Candidate-facing sensitivity levers must be treated as post-calculation scenarios, not primary intake inputs.	US-04
BR-08	The tool must remain traceable to the approved historical data population and methodology version.	US-05
BR-09	Open OGC review items must be resolved before final candidate-facing production use.	US-02, US-04, US-05

5. Open Questions and Release Dependencies

The BRD identifies several items requiring additional input from subject matter experts or OGC before the methodology can be considered final. These items should be tracked as formal release dependencies rather than informal notes.

Open Item	Impacted Story	Required Decision
Make One More Sale Weekly construct	US-04	OGC must validate framing, placement, and labeling on the results screen.
30% Conversion Increase construct	US-04	OGC must validate framing, basis, and presentation.

Market Served table	US-02	OGC must confirm quartile-to-segment mapping and associated income ranges for candidate-facing use.
±10% output band	US-03, US-04	OGC must confirm whether the displayed variability band is appropriately sized or should be changed.
Annual growth rate table	Potential future story	Product must confirm whether future-year projections are in scope or contextual only.
Persistency assumption	Potential future story	Product must confirm whether 98% persistency is shown or used in calculations beyond first-year estimates.

6. Recommended Backlog Structure

For implementation purposes, the five user stories can be decomposed into smaller engineering tasks without changing the business-level story structure. The recommended backlog sequencing is to build the intake form first, then the market mapping configuration, then the calculation engine, then the results experience, and finally the governance and audit controls needed for release.

Sequence	Backlog Item	Related Story	Suggested Owner
1	Build candidate input form and validation	US-01	UX / Frontend / BA
2	Configure market segment table and ranges	US-02	Product / Backend / Data
3	Implement activity position and income range calculation	US-03	Backend / QA
4	Build results screen with base estimate	US-04	UX / Frontend
5	Add scenario toggles as configurable sensitivity views	US-04	Product / Frontend / Backend

6	Add disclaimer, approval controls, and methodology versioning	US-05	Product / Compliance / Engineering
7	Complete OGC review and lock candidate-facing language	US-02, US-04, US-05	Legal/OGC / Product

7. Suggested Additional User Story If Multi-Year Modeling Is Required

The visible BRD includes annual growth rate and persistency assumption sections. If the product scope includes future-year income projections, the following additional story should be added. If the current product is limited to first-year estimates, this story can remain out of scope.

Story ID	User Story	Description	Acceptance Summary
US-06	As a candidate, I want to view future-year projection scenarios so that I can understand how income may grow over time under approved assumptions.	This would use the annual growth rate methodology and 98% persistency assumption if approved for candidate-facing use.	The system must clearly distinguish future projections from first-year estimates, apply approved growth and persistency assumptions, and include disclaimer language.

8. Final Consolidated Acceptance Summary

The solution should be accepted when a recruiter can enter a candidate's profile and activity assumptions, select the intended market, generate a historically bounded first-year income range, optionally view clearly labeled post-calculation scenarios, and provide the candidate with a compliant explanation that the estimate is hypothetical. The underlying system must preserve the approved segment ranges, calculation formulas, data population assumptions, and OGC review status so that every displayed value is explainable and auditable.
